Learn to Code with Ruby

# The split and join Methods

- The **split** method breaks up a string based on a delimiter/separator. It returns an array of the segments of the string.
- The **join** method does the inverse. It concatenates an array's elements into a single string (i.e., it *joins* the elements together).

# String Character Iteration

- Use the `chars` method to return an array of a string's characters. Then, use regular array iteration methods.
- The `each_char` method iterates over each character in a string.

# Additional Methods

- The **count** method counts the number of occurrences of specified characters within a string.
- The **index** method returns the first index position of a substring. The **rindex** method returns the last index position of a substring.
- The **delete** method removes specified characters from a string.
